Autowire field, constructor, Setter

Autowire allows Spring to automatically resolve dependencies by type, injecting the appropriate beans into fields, constructors, or methods.

Steps:

1. Create a @Bean method in the configuration class.
2. Use @Autowired to automatically inject the dependency (in the constructor, field, or method).
3. In newer versions of Spring, the @Autowired annotation can be skipped as Spring performs automatic autowiring by type.

There are several ways to perform autowiring in Spring: **field-level**, **setter-based**, and **constructor-based** injection. Each method has its use case and benefits. Here's a detailed explanation of each, along with the code examples.

1. Field-Level Autowiring

Field-level autowiring is the simplest and most commonly used form of dependency injection. The dependency is injected directly into the field of the class using the @Autowired annotation.

How it works:

- The @Autowired annotation is placed directly on the field.
- Spring will automatically inject the appropriate bean by matching the type of the field with the bean.

Example:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.context.annotation.Bean;
import org.springframework.context.annotation.Configuration;
```

```java
import org.springframework.stereotype.Component;

@Configuration
public class AppConfig {

        @Bean
        public Alien alien() {
        return new Alien();
        }

        @Bean
        public Desktop desktop() {
        return new Desktop();
    }
}

@Component
class Alien {
        @Autowired  // Field-level Autowiring
        private Computer computer;  // Injected by Spring

        public void code() {
       System.out.println("Coding...");
       computer.compile();  // Calls the compile method of injected Computer
         }
}

interface Computer {
        void compile();
}

@Component
class Desktop implements Computer {
        @Override
```

```
        public void compile() {
        System.out.println("Compiling using Desktop");
        }
}

// Main class
public class App {
        public static void main(String[] args) {
        ApplicationContext context = new
AnnotationConfigApplicationContext(AppConfig.class);

        Alien alien = context.getBean(Alien.class);
        alien.code();  // Output: "Coding..." followed by "Compiling using Desktop"
        }
}
```

Key Points:

- **Pros**: Easy to use and clean code.
- **Cons**: Less testable since the field is private, and you cannot pass dependencies through the constructor easily for testing.
- **Use case**: Quick injection where testing flexibility is not a concern.

2. Setter-Based Autowiring

Setter-based autowiring uses setter methods to inject dependencies into a class. It is a good option when you want to have some control over when the dependency is injected.

How it works:

- The @Autowired annotation is placed on the setter method.
- Spring calls the setter method to inject the dependency.

Example:

```
@Component
class Alien {
        private Computer computer;

        public void code() {
       System.out.println("Coding...");
       computer.compile();  // Calls the compile method of injected Computer
        }

        @Autowired  // Setter-based Autowiring
        public void setComputer(Computer computer) {
        this.computer = computer;
        }
}

// Rest of the code remains the same as above
```

Key Points:

- **Pros**: More flexibility and better for testing (you can inject mocks/stubs later).
- **Cons**: Slightly more verbose than field injection.
- **Use case**: When you need to perform additional logic before setting the dependency or if you want to make the dependency optional.

3. Constructor-Based Autowiring

Constructor-based autowiring is considered the best practice by many developers. It ensures that the required dependencies are injected when the object is created, making the object immutable after construction.

How it works:

- The @Autowired annotation is placed on the constructor. In Spring 4.3+, if a class has only one constructor, you can omit the @Autowired annotation.
- Spring automatically injects the necessary dependencies into the constructor.

Example:

```
@Component
class Alien {
        private final Computer computer;

        // Constructor-based Autowiring
        @Autowired
        public Alien(Computer computer) {
        this.computer = computer;  // Dependency injected through constructor
        }

        public void code() {
       System.out.println("Coding...");
       computer.compile();  // Calls the compile method of injected Computer
         }
}

// Rest of the code remains the same as above
```

Key Points:

- **Pros**:
    - Enforces dependency injection at the time of object creation, making the object immutable.
    - Makes the class easier to test by passing mock objects in the constructor.
    - In newer versions of Spring, @Autowired can be omitted if the class has a single constructor.
- **Cons**: Slightly more code to write, but it is the preferred method in many cases.
- **Use case**: When you want to ensure immutability and the dependency is mandatory.
